

ZedX - What I Found Testing the App

Hi, here's a rundown of what I found going through the ZedX app. I tested every page by hand - Mint, Swap, Buy, Sell, Limit, Trade, Staking, and Markets - with the browser's DevTools open so I could see exactly what was happening behind the scenes, not just what the page showed. Where something looked off, I also checked the backend directly to see whether the problem was on the frontend side or the backend side.

Quick note on the setup: this app's contracts are live on Polygon Mainnet, so everything below is from testing against the real, live blockchain, no test network involved.

Short version: Mint, Swap, Buy, Sell, and Limit all have problems. Trade works, but it's not actually talking to its own backend. Staking and the live price feed both work fine. The good news is most of these bugs come from just a couple of root causes, not five completely separate problems, I've broken that down at the end.

Mint - price shown as "Free," and it isn't

The Mint page shows "Mint price: Free." That's wrong. I checked the actual price against the backend:

```
GET /api/v1/staking/info
mint_price_wei: 1000000000000000000 = 1 POL per ZEDX
```

Someone using this page would expect to pay nothing and then get surprised by a wallet prompt, or hit the mint bug below and just get a failure with no explanation.

Same screenshot below also shows the supply bar sitting empty. Current supply was 1,000,201.53 / 1,000,000,000, which is about 0.1%, a real number, just small. The bar should show a sliver but shows nothing, which looks like a rounding issue (anything under 1% collapsing to 0 width). Minor, but it makes the page look stuck.

Mint page - price shows Free, progress bar empty

Swap, Buy, Sell - none of them produce a quote

Tried Swap (ETH to USDC) and Buy (USDT to ETH), both fail the same way:

```
GET /api/v1/swap/quote?from=ETH&to=USDC&amount_in=1
-> address must be 20 bytes (40 hex chars)
```

The backend wants a real token contract address (or the words "native"/"zedx"), and the frontend is just sending plain symbols like "ETH" and "USDC" with nothing translating them first. That's why every token pair fails.

Worth ruling out up front: this isn't a wallet-connection problem. The "Connect Wallet" button was still showing when the error happened, so no wallet was involved yet, the quote request runs before any of that.

One difference between the pages: Buy shows the error to the user in red text. Swap doesn't show anything visible, the button quietly changes its label to "No route found," but a user would probably just think the page is stuck.

Swap page - error in Network tab

Buy page - error shown in red text

Sell has a different, second bug on top of this. The page has quick-fill buttons, 25%, 50%, 75%, Max, meant to fill in a portion of your balance. Clicking "50%" doesn't calculate anything, it just puts the literal text "50%" into the amount field, and that string gets sent straight to the backend as-is:

```
GET /api/v1/swap/quote?from=ETH&to=USDT&amount_in=50%  
-> amount_in must be a base-10 integer string
```

So even once the address-mapping bug is fixed, the percentage buttons on Sell will still be broken, they need to actually calculate a number from the wallet's balance instead of inserting a percent string.

Sell page - percentage button sends "50%" as the amount, distinct error

Limit - the page isn't wired up at all

Went to the Limit tab, typed 1 as the limit price, 1 as the Sell amount (ETH), left Buy on USDT. Nothing happened, Buy field just sat at 0. Clicked "Place limit order," also nothing, no request, no error, no feedback of any kind.

Also tried clicking directly into the Buy field to type an amount there myself, it's not clickable at all. Checked the code to see why: the Buy field on this page isn't an input, it's just static text that always displays 0. There's no quote logic here, and the "Place limit order" button has nothing attached to it either, clicking it doesn't call anything.

So this isn't the same bug as Swap/Buy/Sell (which at least try to fetch a quote and fail). This page was never finished, it's a UI shell with no logic behind either the Buy field or the submit button.

There's also a disclaimer at the bottom saying "Only Ethereum mainnet tokens are available for limits," which doesn't make much sense on a Polygon app and doesn't explain the lack of activity either.

Limit page - Buy field stuck at 0, button does nothing

Trade - the UI doesn't talk to its own backend

The backend actually has a working order book. I tested it directly:

```
POST /api/v1/orders {"market_id":"btc-usdt","side":"buy","order_type":"market","size":"0.01"}  
-> order created (came back cancelled since there were no matching sell orders, expected on an empty book)  
  
GET /api/v1/orders?market_id=btc-usdt  
-> order shows up correctly
```

So the backend side works. But the Trade page in the browser never calls it. Placing an order just writes to localStorage, no network request at all. Which means your trades never reach the real order book and nobody else would ever see them.

To be clear, this is only about placing orders, the price feed, chart, and live ticker are a separate system and they work fine (see below).

This might be on purpose, the docs do call it "paper trading," but it's worth double-checking with you, since it doesn't match what you'd expect from something that looks like a live, connected order book.

Markets / price feed - works

Checked /markets, /trade/btc-usdt, the WebSocket connection, and a handful of the 34 pairs that mirror live Binance prices. Prices update roughly every 2 seconds, chart renders, order book and recent trades display correctly. No issues here.

Staking - reads work, one flaky moment

Hit the staking info endpoint 4 times. 3 came back fine instantly:

```
APR: 12%  
Total staked: 11,004 ZEDX  
Reward pool: 1,000,000 ZEDX
```

One came back completely empty, no error, before the next call worked normally. Probably just the public RPC endpoint hiccupping, not an app bug, but the staking page doesn't show any error or retry when this happens, so a user hitting that exact timing would just see blank numbers with no explanation.

Haven't tested the actual staking actions (approve, stake, unstake, claim, exit), need a wallet with ZEDX and POL for gas, and getting ZEDX in the first place is blocked by the mint bug above unless there's another way to get some.

What's actually causing all this

Four root causes cover everything above:

1. **Frontend sends token names instead of real contract addresses.** This is what breaks Swap, Buy, and Sell. One fix (a symbol-to-address lookup table) should cover all three.
2. **Mint doesn't match how the deployed contract actually works.** Needs the frontend call reworked to send the right payment and match the real contract.
3. **Limit was never finished.** No quote logic, no submit handler. Needs to be built from scratch, and it'll want the same address-lookup fix from #1 once it exists.
4. **Trade doesn't call its own backend.** This is more of a product decision than a bug. Does the team want a real shared order book, or is local-only paper trading intentional? Once that's decided, the fix is straightforward.

Plus a few smaller things: the mint progress bar rounding, staking silently swallowing read errors, and Sell's percentage quick-fill buttons sending a percent string instead of a calculated amount.

What still needs a funded wallet

Couldn't test these without spending real POL (no test network exists for this project):

- Actually completing a mint (expected to fail per the bug above)
- Actually completing a swap/buy/sell (blocked by the same root cause regardless of funding)
- The full staking cycle: approve, stake, wait for rewards, claim, exit
- Wallet edge cases: wrong network, switching mid-session, rejecting a transaction, running out of funds

If you want these tested too, it just needs a small test wallet with a few dollars of POL in it, happy to run through that list once that's set up.

Happy to walk through any of this or go deeper on a specific page if useful, just let me know.
